 genome

distributed in adjacent Chinese provinces of Hainan, Guangxi,
 Jiangxi and Guangdong (Fu 2014).

Mitochondrial genome sequences are essential to a deeper
 understanding of the evolution of Lampyridae and other lumi-
 nescent beetles (Ermakov et al. 2006). Here, we elucidate the
 mtDNA genome of *A. circumdata*.

Specimens were collected from Guangxi Province, China
 (23°24'N, 108°22'E) and were stored in Natural History

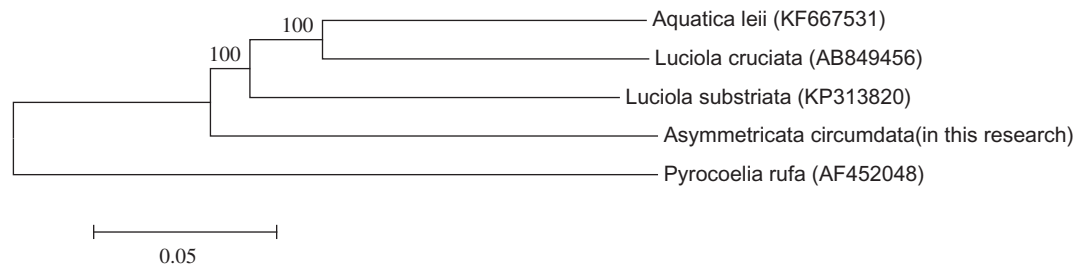

Figure 1. Molecular phylogeny of *Asymmetricata circumdata* and four other firefly species based on the complete mitochondrial genome. The complete mitochondrial genome was downloaded from GenBank and the phylogenetic tree was constructed by Neighbour-Joining method with 1000 bootstrap replicates. MtDNA accession numbers used for tree construction are as follows: *Aquatica leii* (KF667531), *Luciola cruciata* (AB849456), *Luciola substriata* (KP313820), *Pyrocoelia rufa* (AF452048).

Museum, Huazhong Agricultural University, Wuhan, Hubei, China (its accession no. is AC2014071301). As a species of steady-state bioluminescence fireflies, its habits, flashing signals and some morphology have been studied in detail (Wattanachaiyingcharoen et al. 2012; Goswami et al. 2015). However, there is no genetic research information about *A. circumdata*.

Specific primers were designed based on these conserved regions sequences. The PCR reaction was carried out with LA Taq polymerase for 35 cycles at 94 °C for 30 s, and annealed at 50 °C for 30 s, followed by extension at 72 °C for 1 min per 1 kb. Sequences were assembled using the software DNASTar v7.1 (Madison, WI) and adjusted manually to generate the complete sequence of mitochondrial DNA.

The complete mitochondrial genome sequence of *A. circumdata* (GenBank KX229747) has 15,967 bp and has a base composition of A (42.44%), C (12.83%), G (8.79%), T (36.16%). Similar to other Metazoa, our sequence contains 13 protein-coding genes, 22 transfer RNA genes, 2 ribosomal RNA genes and a non-coding AT-rich region, which represents a typical insect mitochondrial genome (Wolstenholme 1992). The open frames of the 13 protein-coding genes were inferred from three other fireflies: *Aquatica leii*, *Luciola substriata* and *Pyrocoelia rufa* (Lee et al. 2004; Jiao et al. 2013; Mu et al. 2015). All 13 PGGs initiated with ATN (ATT, ATA and ATG) codon, while 8 PGGs stopped with TAA or TAG codon, and the other 5 PGGs have an incomplete termination codon, namely, a single T (Table 1). The AT-rich region is 1388 bp,

which is shorter than that of the other fireflies with reported sequences.

The phylogenetic tree among the five species based on mitochondrial genome sequences were aligned in MEGA 5 (Phoenix, AZ) (with 1000 bootstrap replicates) to construct a Neighbour-Joining tree (Figure 1).

The result shows *A. circumdata* is most closely related to *L. substriata*, which belongs to an entirely different genus in the Lampyridae.

In conclusion, the complete mitochondrial genome sequence of *A. circumdata* provides an important molecular framework for further phylogenetic analyses of fireflies. These data are essential for deeper understanding of the role of sexual and natural selection in the evolution of firefly flashing signals.
